

PROJECT TITLE: Frozen-in: characterising the micro-environment of ice inhabiting microbes

DTP Research Theme(s): Living World, Changing Planet

Lead Institution: University of Bristol

Lead Supervisor: Dr Chris Williamson, Bristol Glaciology Centre, School of Geographical Sciences, University of Bristol

Co-Supervisor: Dr Liz Thomas, Ice Core Group, British Antarctic Survey, Cambridge

Project Enquiries: c.williamson@bristol.ac.uk

Project keywords: cryosphere, glaciers, microbes, ice cores, biogeochemistry

Morteratsch glacier, Switzerland (summer 2020), where abating ice harbours both ancient and contemporary microbial communities within the weathered ice surface.

Drilling shallow ice cores on Bouvet Island, South Atlantic. Ice cores from the sub-Antarctic islands and Antarctica will be used in this project.

Project Background

Permanently cold ecosystems make up more than 70% of the Earth's biosphere, though paradoxically, the microorganisms that thrive in these extreme habitats are the most poorly understood. Whilst we are beginning to gain an understanding of the diversity and functioning of key microbial groups that dominate across the cryosphere, several key questions remain unanswered. For example, what is the micro-environment experienced at the scale of an individual cell that lives within a complex snow or ice matrix? How has this shaped their physiological capabilities and survival strategies? And how does this vary between different cryospheric habitats (snow to firn to glacier ice), throughout freeze-thaw cycles, or with long-term burial within glaciers? Answers to these questions are important not just for learning about the ecophysiology of extremophile microbial communities, but also to provide critical contextual knowledge on the interactions between microbial communities and key physical (snow/ice formation, melt and fine-scale structure) and chemical (carbon and nutrient cycles) processes within the cryosphere.

Project Aims and Methods:

This studentship will characterize the distribution and micro-environment of snow and ice inhabiting microbial communities, in order to enhance understanding of their true physiological capabilities, survival strategies, and interactions with key physiochemical processes. During Year 1, the student will characterise the fine-scale spatial distribution and micro-environment of microbes residing within supraglacial environments (snow, weathered surface ice and shallow sub-surface ice cores). Sample processing will proceed in the University of Bristol's MicroLab and Biogeochemical facilities, and the British Antarctic Survey's class-100 clean room and cold room facilities, with training

provided in all relevant methodologies (see below). During Year 2, the student will conduct manipulative experiments to examine micro-environment development and microbial physiological responses during ice formation and freeze-thaw cycling, using the UoB's Low Temperature Experimental Facility (LOWTEX). Finally in Year 3, the student will extend the knowledge gained by characterising ancient microbial communities along Alpine, Arctic and Antarctic ice cores to uncover long-term responses to burial within glacier ice and potential viability with the onset of melt.

This interdisciplinary project unites the MicroLab research group of the Bristol Glaciology Centre, with the Ice Core Group of the British Antarctic Survey (BAS). The successful candidate will spend significant time at BAS and be integrated into the ice core team. Additional to the extensive infrastructure and scientific resources that BAS brings to this project, the student will benefit from full exposure to this world-leading research institution.

Candidate requirements: This project will suit a student with a first-class degree in physical geography, earth or biological sciences, with experience in one or more of the following: microbiology, biogeochemistry, glaciology, remote field work campaigns. *We welcome and encourage student applications from under-represented groups. We value a diverse research environment.*

Training: The student will receive extensive training in remote field-work techniques, microbial imaging, enumeration and identification, snow/ice physics, biogeochemical analyses, ice-core and cold room practices. Candidates will emerge with a strong background in interdisciplinary sciences including advanced field and laboratory skills. A demonstrable track-record in highly marketable transferable skills, including numeracy, written and spoken presentation, and an ability to work effectively within a multidisciplinary team will also be developed. The student will have extensive opportunities for overseas travel for both networking (conferences) and fieldwork purposes.
