## A. MultiMam kit contents

- **Plasmid acceptor vectors**

pACEMam1, pACEMam2; approx. 2 µg DNA per vial (in buffer solution)

keep at 4°C for short-term storage and in a freezer at -20°C or lower for medium- and long-term storage (take care to avoid repeated freeze-thaw cycles, e.g. by aliquotting DNA prior to freezing)

- **Plasmid donor vectors**

pMDC, pMDK, pMDS; approx. 2 µg DNA per vial (in buffer solution)

keep at 4°C for short-term storage and in a freezer at -20°C or lower for medium- and long-term storage (take care to avoid repeated freeze-thaw cycles, e.g. by aliquotting DNA prior to freezing)

- **E. coli strains as agar stabs**

a) transformed with acceptor and donor vectors (5 vials)

For plating bacteria as a starting point for plasmid preparation

b) pirHC, pirLC cells<sup>†</sup>

For propagation and amplification of donor multi-gene expression constructs or donor-donor fusions

Keep agar stabs at 4°C or at RT; **do not freeze!** We recommend to immediately prepare stocks from streaked bacterial colonies (see p. 26).

<sup>†</sup> *E. coli* strains expressing the *pir* gene for propagation of donor vectors (any other strain with *pir*<sup>+</sup> background can be used as well). LC: low copy number propagation, HC: high copy number propagation of plasmids with R6K $\gamma$  origin.

## Reagents to be supplied by the user (see also section D. Protocols)

- Restriction enzymes
- Homing endonucleases PI-SceI and I-CeuI
- Mammalian cells, e.g. HEK293, CHO, etc.
- T4 DNA ligase
- Cre recombinase
- Standard *E. coli* strains for cloning (such as TOP10, DH5 $\alpha$ , HB101 etc.)
- Standard laboratory buffers, solutions, media and equipment for bacterial and mammalian cell culture, transformation etc.
- Commercially available transfection reagents, e.g. FuGENE® (Roche), jetPEI™ (Polyplus transfection), etc. or an apparatus for electroporation
- Antibiotics

## B. Introduction

### Cellular interaction networks and protein complexes

Life is complex, in more than one way - not only in terms of the number of interactions between cellular and subcellular components, e.g. proteins, but also in that it hinges critically on the function of organized macromolecular complexes. In 1998, Bruce Alberts confronted conventional thinking that predicated on the action of individual proteins on Beadle and Tatum's one-gene/one-enzyme hypothesis (published in 1941) which for decades had shaped much of biological research. Instead, Alberts ask to direct the focus to a modular cellular machinery composed of protein complexes (Alberts, 1998).

Proteins are the physical representatives of the information encoded by their corresponding genes and mRNAs. They are themselves embedded into a tightly and intricately regulated DNA-RNA-network (Vidal et al., 2011). These proteins determine many structural and physiological properties of cells but rarely act in isolation to mediate their effects. More often than not they will have multiple partners - not only proteins but also nucleic acids and small molecules – which they bind or bind to or associate with in larger complexes.

Whether you look at replication, transcription, translation, transport processes across internal and external membranes, signaling events, etc. - protein complexes come into play in all of these processes. More importantly, such complexes – if disrupted by mutations or the like - also engender often severe physiological deficits (Ehmsen et al., 2002; Vidal et al., 2011). Some of these complexes will, by their functional nature, either be long-lived („stable“) or transitory. Fleeting interaction of proteins, e.g. in cell signaling, will result in only minute amounts of a protein complex that usually also exists for only a limited period of time.

Disentangling this social life of the cell (Robinson et al., 2007) is a daunting task but has been tackled with high resolution imaging and analysis techniques (cryoEM, X-ray crystallography, NMR, mass spectroscopy, etc.). Extensive bioinformatics work-up and computer modeling support the experimental structural biology work and contribute to solving complex multi-subunit assemblies down to the atomic level (e.g. Imasaki et al., 2011). All these results enter into a better understanding of molecular interactions between proteins

and other macromolecules, now known as the **interactome** (Figeys, 2008; Charbonnier et al., 2008) and their effects on the biological system of the cell.

## Multi-protein expression tools

Various heterologous systems have been developed for the major production/host organisms *E.coli*, yeast, insect and mammalian cells. While sophisticated system for expressing individual proteins exist, the repertoire of tools for multi-protein expression to date is rather limited (e.g, Bieniossek et al. 2009; Trowitzsch et al., 2010), especially for mammalian cells.

This cell culture of transgene-expressing cells has become one of the mainstays of functional investigations in cellular physiology and biochemistry. Co-transfection, whether by biochemical or physical means or through viruses, still is the method of choice when it comes to delivering genes of interest into mammalian cells. Co-transfection often fails to warrant uniform and constant expression of all vectors in one transfection experiment. Stable transfection remedies this problem to a certain degree but is cumbersome and requires multiple rounds of selection and re-culturing to yield uniform and stable clones.

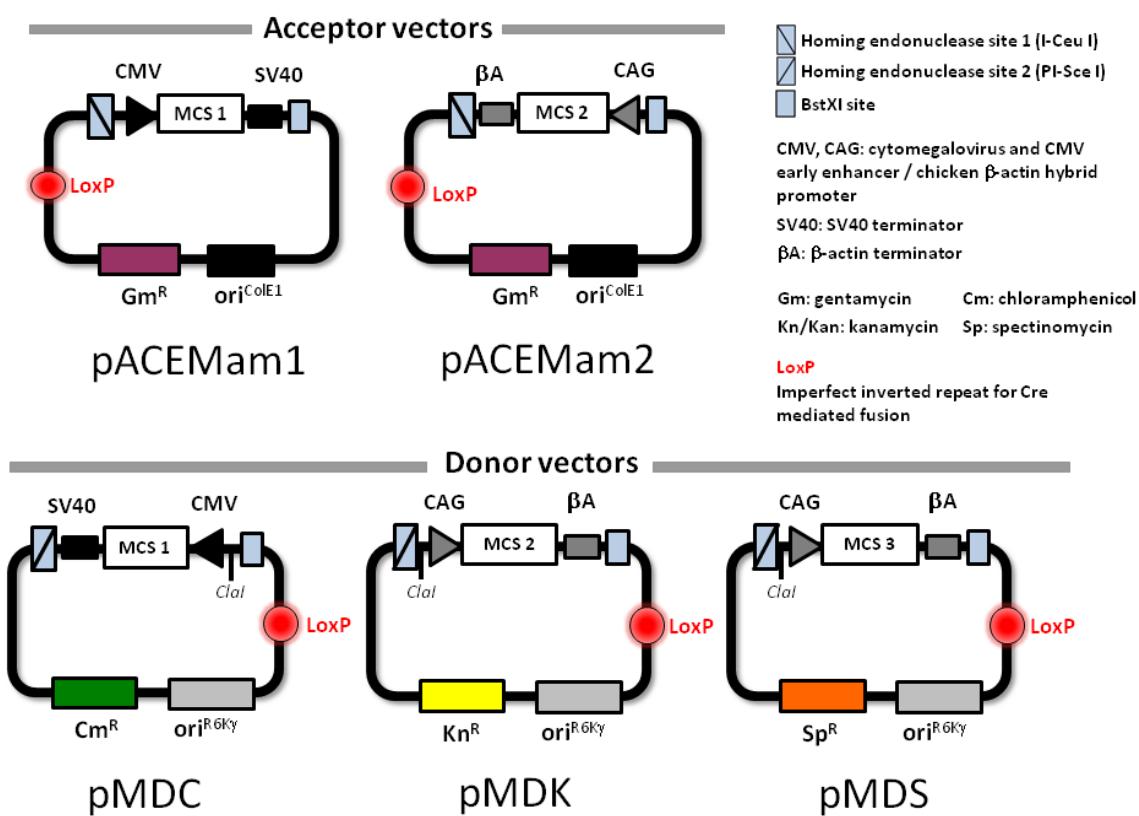

Vector systems that enable uniform transient and, potentially, also stable transfection of multiple genes are in demand. This manual introduces a set of novel mammalian transfer vectors that specifically enable multi-gene applications.

The role of protein interaction networks (the so-called **interactome**; reviewed e.g. in has become an intense focus of biological research efforts in the post-genomic era. Many of the identified multi-protein complexes are expressed at only low abundance in their native cells. This makes analysis of their structure difficult, but this can be remedied by using recombinant technologies to facilitate large-scale heterologous protein production. Currently, recombinant expression methods require a disproportionate investment in both labor and materials prior to multi-protein expression, and, once expression has been established, provide little or no flexibility for rapidly altering the multiprotein components, which is a prerequisite for revising expression studies.

The mammalian expression system introduced here (see also Vijayachandrain et al., 2011) sports two major advances that are instrumental in fully exploiting the potential of this heterologous protein production system:

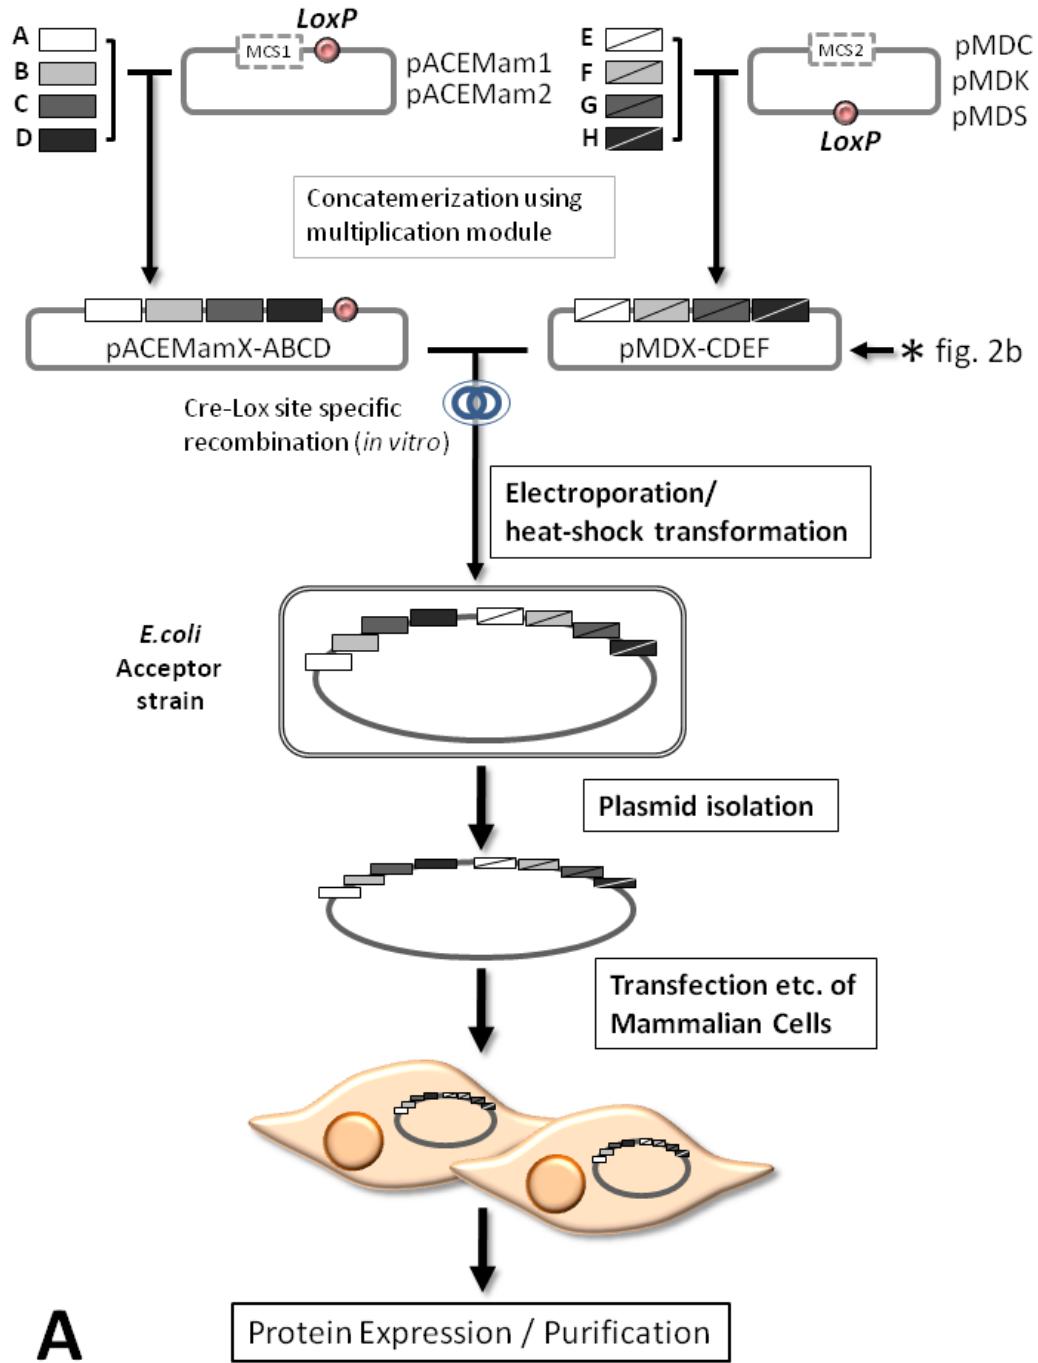

**1.** New transfer vectors (pACEMam1, pACEMam2, pMDC, pMDK, pMDS; see figure 1) that contain a homing endonuclease-based multiplication module. These vectors greatly

facilitate modular combination of heterologous genes (in their respective gene expression cassettes) with a minimum requirement for unique restriction sites (BstXI). Strong viral/mammalian promoters (currently CMV and the hybrid CAG promoters) can be exchanged in our vectors for other promoter sequences if desired. Likewise, terminator sequences (currently SV40, rabbit β-actin) can be substituted as required.

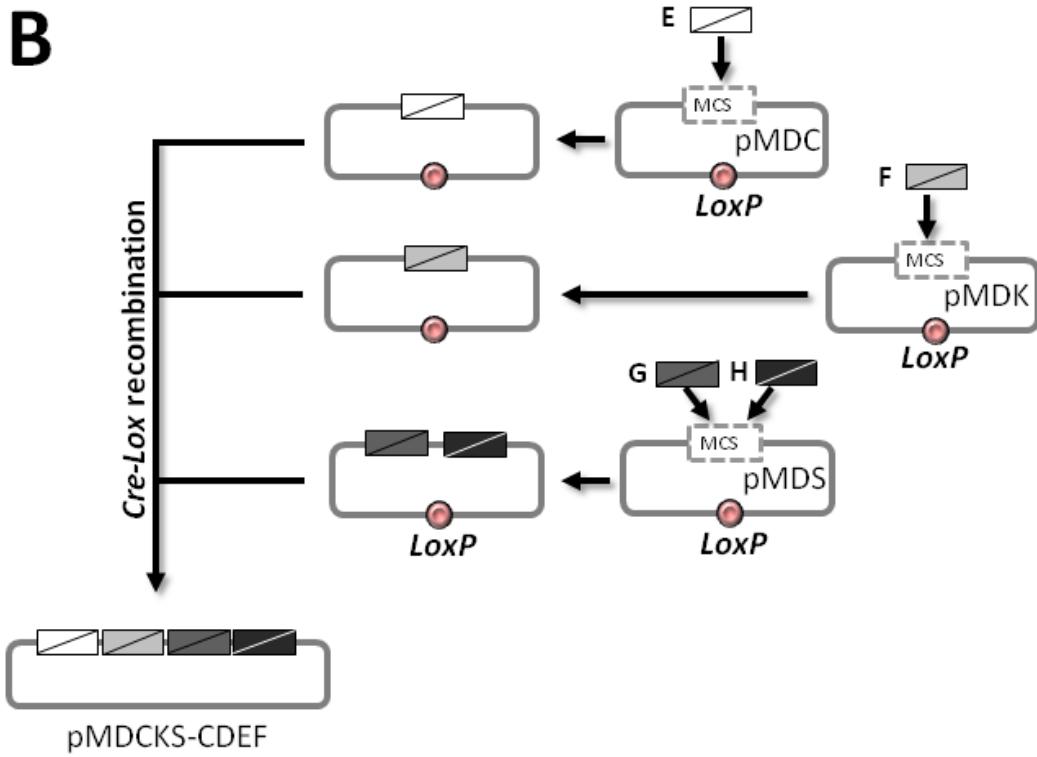

**Figure 1:** Schematic representation of the *MultiMam* acceptor and donor vectors. More detailed vectors maps and sequence information can be found in chapter C (p. 10) and in the appendix (chapter E, p. xxx).

**2.** New protocol for rapid generation of multi-gene expression constructs via Cre-LoxP recombineering. The resulting multi-gene fusion can then be transfected directly into mammalian cells for transient expression. This protocol can be used to integrate multi-gene cassettes with coding sequences for multi-protein complex subunits but also to integrate specific enzymes (kinases, acetylases etc.) for modifying the proteins under investigation.

**Figure 2a: Schematic overview of the MultiMam system and its application.**

Genes of interest are assembled into multigene expression cassettes using the multiplication module present on the donor (pMDC, pMDK, pMDS) and acceptor vectors (pACEMam1, pACEMam2). Acceptor-donor fusions can then be generated by Cre-LoxP recombination. These multigene fusions contain one Acceptor and one to several Donor vectors, each with one or several genes of interest (here A-H). Desired Acceptor-Donor combinations are identified by transformation into *E.coli* and subsequent antibiotic selection. *LoxP* sites in the acceptor-donor fusions have been omitted for reasons of clarity.

**Figure 2B: Generation of multi-gene donor constructs through Cre-Lox fusion.**

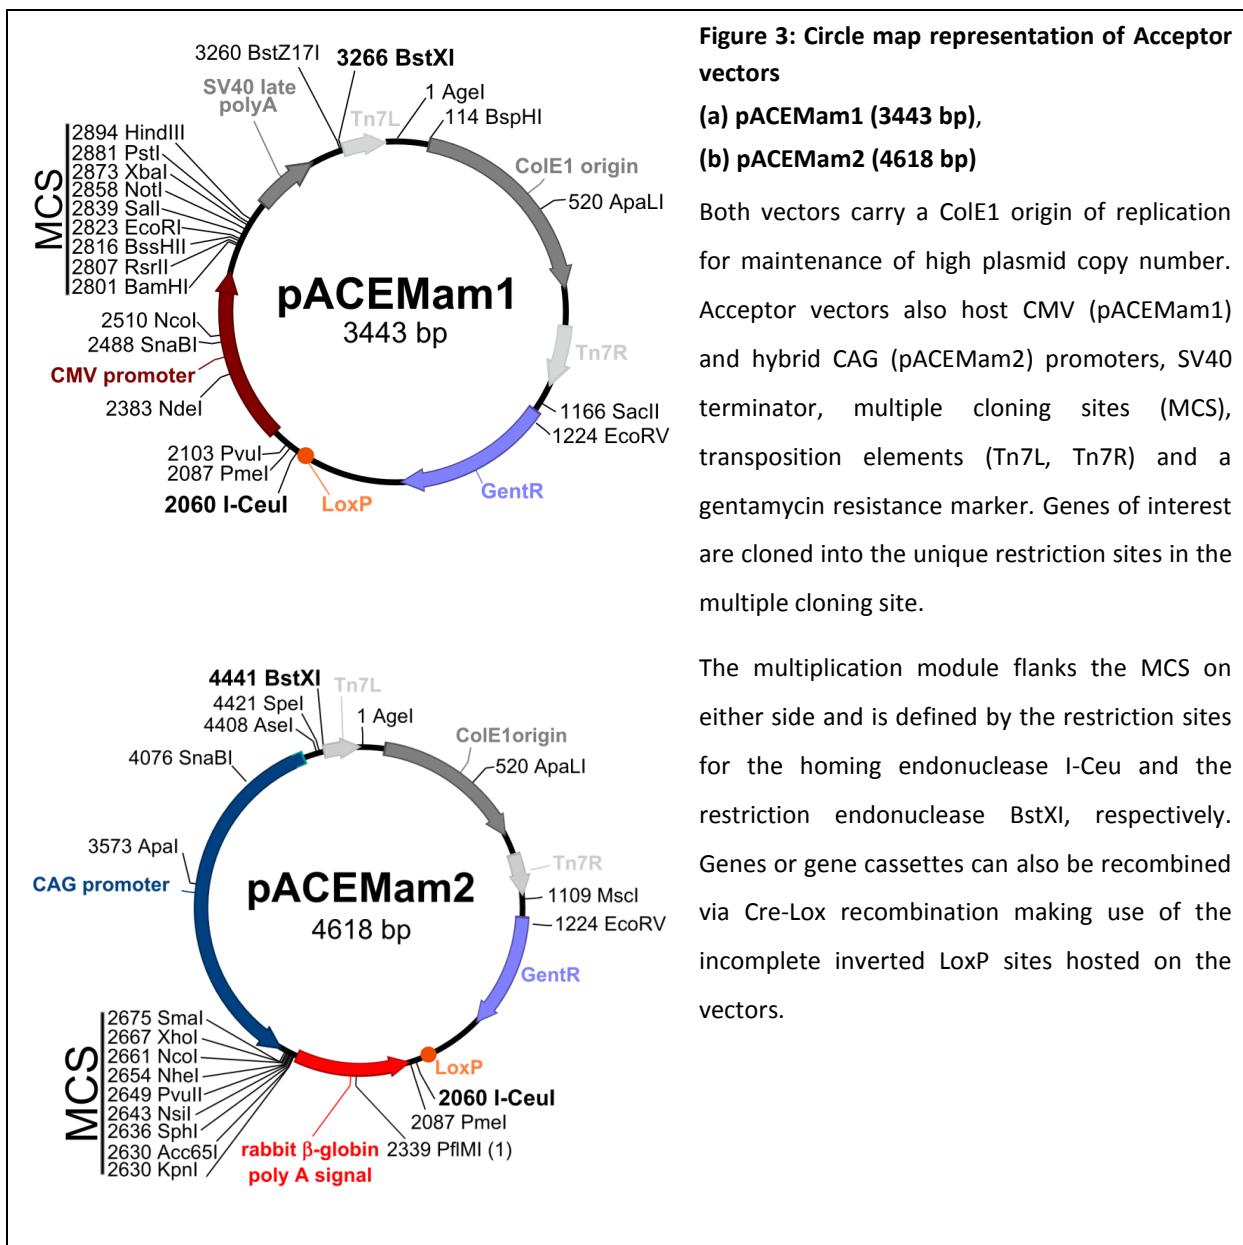

As indicated in figure 2A, donor multi-gene expression cassette constructs can also be generated by Cre-Lox recombination. Individual or multiple gene cassettes are cloned into the multiple cloning site via standard restriction-ligation cloning or, when introducing multiple gene cassettes, homing endonuclease /BstXI cloning. The gene cassettes harbored on different donor vectors are then merged into a single vector construct via Cre-Lox recombination. This construct will differ from the multi-gene constructs in figure 2a with respect to selective markers. While the multi-gene construct in fig. 2A carries only one antibiotic resistance marker, the construct in fig. 2B will carry three, one from each donor vector. This will allow selection of multi-gene constructs with higher stringency by subjecting the constructs to a multi-antibiotic selection regimen (refer to protocol 2). *LoxP* sites in the donor fusion have been omitted for reasons of clarity.

## C. New Tools for Multigene Applications in Mammalian Cells

### C.1. Transfer vectors: the Acceptor-Donor recombineering system.

The **Acceptor vectors** pACEMam1 and pACEMam2 contain multiple cloning sites (MCS; see appendix) flanked by either a CMV or CAG promoter to drive high-level expression in mammalian cells. Wherever necessary, appropriate polyA signal sequences are available (SV40 late for pACEMam1).

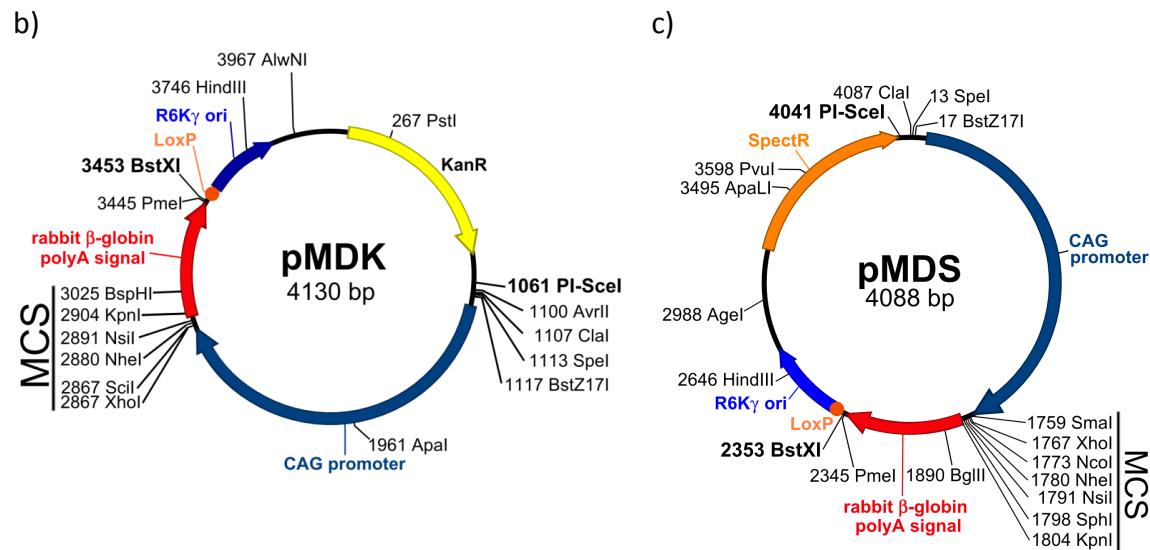

A multiplication module M – defined by the homing endonuclease site I-Ceu and a corresponding BsXI site (see figure 3) – allows integration of multiple gene cassettes (ORFs and associated regulatory regions).

The **Donor vectors** pMDC, pMDS, pMDK are similar to the acceptor vectors with respect to their over-all design. The multiple cloning site is bracketed by a multiplication element (in this case, PI-SceI / BstXI) to enable concatenation of inserts between the different donor vectors. Vectors also contain a LoxP incomplete inverted repeat to create acceptor-donor or donor-donor fusions. The vectors contain “tell-tale” resistance markers (pMDC: chloramphenicol, pMDK: kanamycin, pMDS: spectinomycin) and, importantly, a conditional R6K $\gamma$  origin of replication which makes propagation of the donor vectors dependent on the expression of the *pir* gene in the prokaryotic host (such as the pirLC and pirHC cells contained in the kit).

**Figure 4: Circle map representation of Donor vectors a) a)  
pMDC, b) pMDK, c) pMDS.**

Circle maps show promoters (CMV, CAG), terminators (SV40, rabbit  $\beta$ -globin), multiple cloning sites (MCS), the incomplete inverted repeat for *cre-lox* site-specific recombination (LoxP) and resistance markers (chloramphenicol, kanamycin, and spectinomycin, respectively). Genes of interest are cloned into the MCS using unique restriction sites. The multiplication module consists of the homing endonuclease site PI-SceI and the restriction endonuclease site BstXI. All donor vectors host a conditional R6K $\gamma$  origin of replication.

The ACEMBL system vectors in their current form do not contain DNA sequences that code for affinity tags (that will facilitate purification or solubilization of the protein(s) of interest). Tags that are typically used are C- or N-terminal oligohistidine tags, with or without protease cleavage sites for tag

removal. They can be introduced by designing the respective PCR primers used for amplification of the genes of interest. We recommend outfitting Donors or Acceptors of choice with any custom tag that is favored in individual user laboratories prior to inserting recombinant genes of interest. This is best done by using a design that will, after tag insertion, still be compatible with the recombination-based principles of ACEMBL system usage.

The same holds true for reporter genes, most notably fluorescent proteins that are commonly used in protein localization or protein interaction studies. These can also be fused to your protein under investigation using PCR techniques.

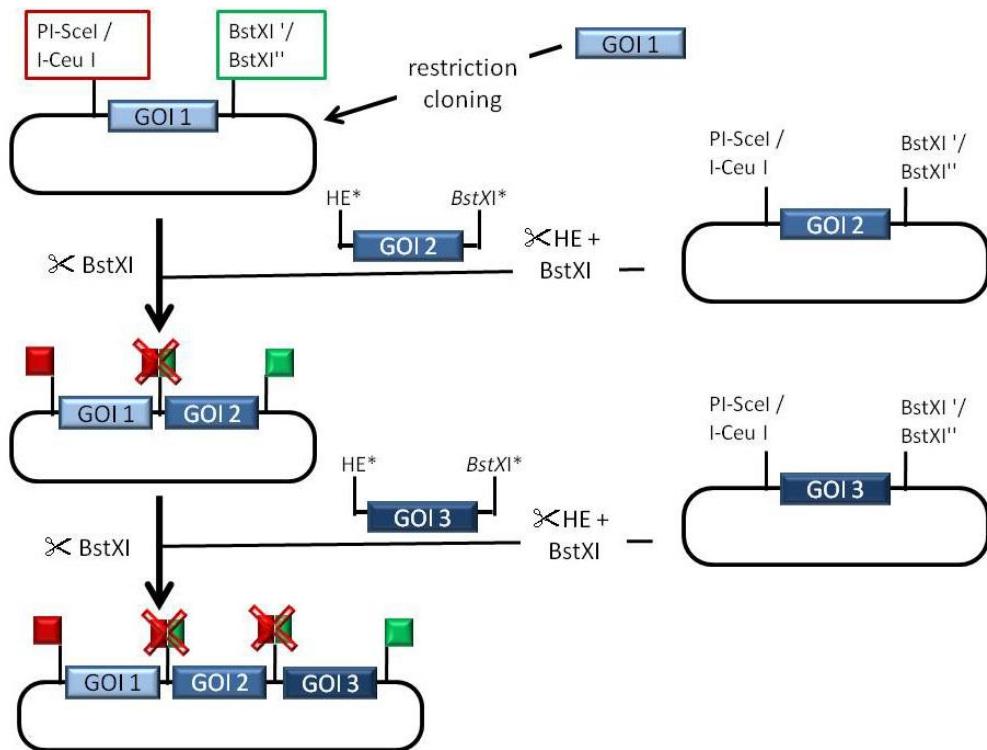

## C.2. Generating multi-gene expression cassettes

### C.2.1. Using the homing endonuclease/*BstXI* multiplication module

The acceptor and donor vectors are suited for generating multi-gene expression cassettes from individual gene expression cassettes (complete with regulatory regions such as promoter and terminator) via a multiplication module bracketing the multiple cloning site (MCS). All *MultiMam* vectors contain a homing endonuclease (HE) site and a correspondingly designed *BstXI* site that together bracket the MCS. Homing endonucleases have long recognition sites (20-30 base pairs or more). Although not all equally stringent, homing endonuclease sites are very likely unique in the context of even large plasmids, or, in fact, entire genomes.

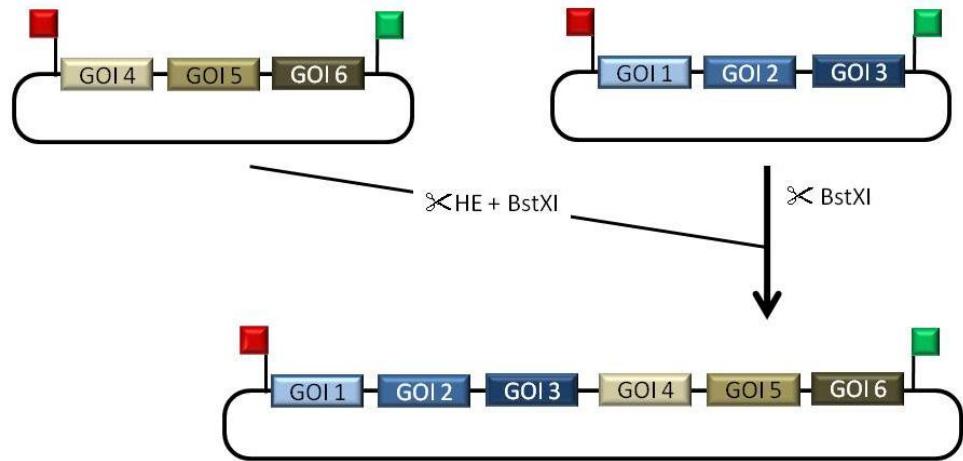

The logic of multiplication is illustrated below. The homing endonuclease site can be used to insert entire expression cassettes into a vector that already contains one gene or several genes of interest as separate expression cassettes. The only prerequisite for assembling multi-gene expression cassettes is that the homing endonucleases and restriction enzymes used for multiplication (*I-CeuI/PI-SceI* and *BstXI*) are unique, which can be easily accomplished, for instance by site-directed mutagenesis prior to multi-gene cassette assembly. First, individual genes are cloned into the multiple cloning sites of the acceptor and donor vectors. The entire expression cassette, including promoter and terminator, is then excised by *I-CeuI* / *BstXI* (acceptors) or *PI-SceI* / *BstXI* (donors) digestion. The resulting fragment is placed into the multiplication module of another acceptor or donor vector containing single or multiple gene cassettes. The restriction sites involved are eliminated in the process and multiplication can be repeated iteratively using the module present in the inserted cassette. Moreover, promoter and terminator sequences can be easily modified if desired using appropriate restriction sites in our vectors.

- !** Please note that multiplication cannot be accomplished from donors to vectors and vice versa
  - since the overhangs generated by endonuclease digestion are incompatible.

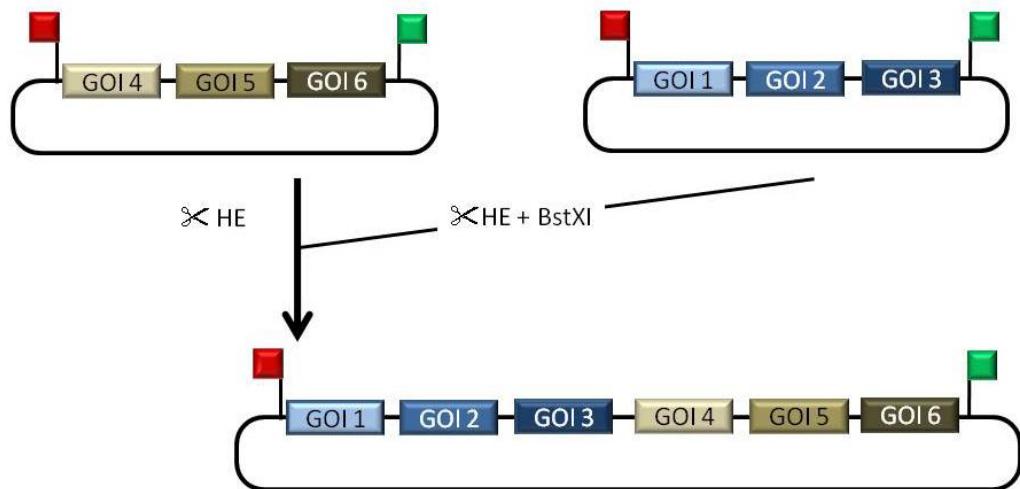

**Figure 5: Assembling individual gene cassettes into multigene expression cassettes.** The logic of multiplication is shown schematically. The expression cassette containing the gene of choice (denoted as GOI2 in this case) is excised by digestion with the homing endonuclease (red box) and BstXI (green box). For acceptor vectors, I-CeuI is the homing endonuclease of choice, and for donor vectors PI-SceI. The plasmid vector harboring the GOI1-cassette only needs to be linearized with BstXI. The homing endonucleases produce cohesive ends that are compatible with the ends generated by the BstXI digest. Upon insertion of GOI2 into the target vector, a homing endonuclease/BstXI hybrid restriction site is created that can then cannot be cut by either enzyme (crossed-out red/green box) while the 3'-BstXI site is regenerated. The same procedure can be repeated over and over as exemplified by the integration of GOI3. This cycling logic can be used to generate multi-gene assemblies. Note that the promoters and terminators are not explicitly shown for reasons of clarity.

A

B

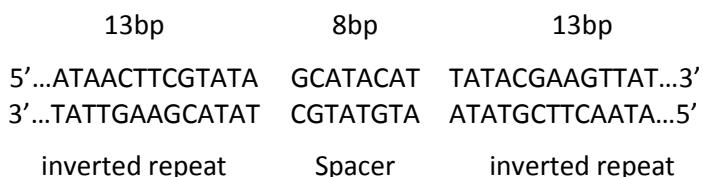

**Figure 6: Combining multigene expression cassettes.** Different multi-gene expression cassettes can be combined into one expression construct following the same logic that applies to the generation of multi-gene expression cassettes from individual gene cassettes (figure 4). The 5' homing endonuclease recognition site (filled red box) will be preserved if GOI1 has been introduced by conventional restriction cloning into the MCS. Promoters and terminators are not explicitly shown for reasons of clarity but flank the GOIs in every individual gene expression cassette.

### C.2.2. Multi-gene construction using Cre-Lox recombination

Cre recombinase is a member of the integrase family (Type I topoisomerase from bacteriophage P1). It recombines a 34 bp loxP site in the absence of accessory protein or any auxiliary DNA sequence. The loxP site is comprised of two 13 bp recombinase-binding elements arranged as inverted repeats which flank an 8 bp central region where cleavage and the ligation reaction occur.

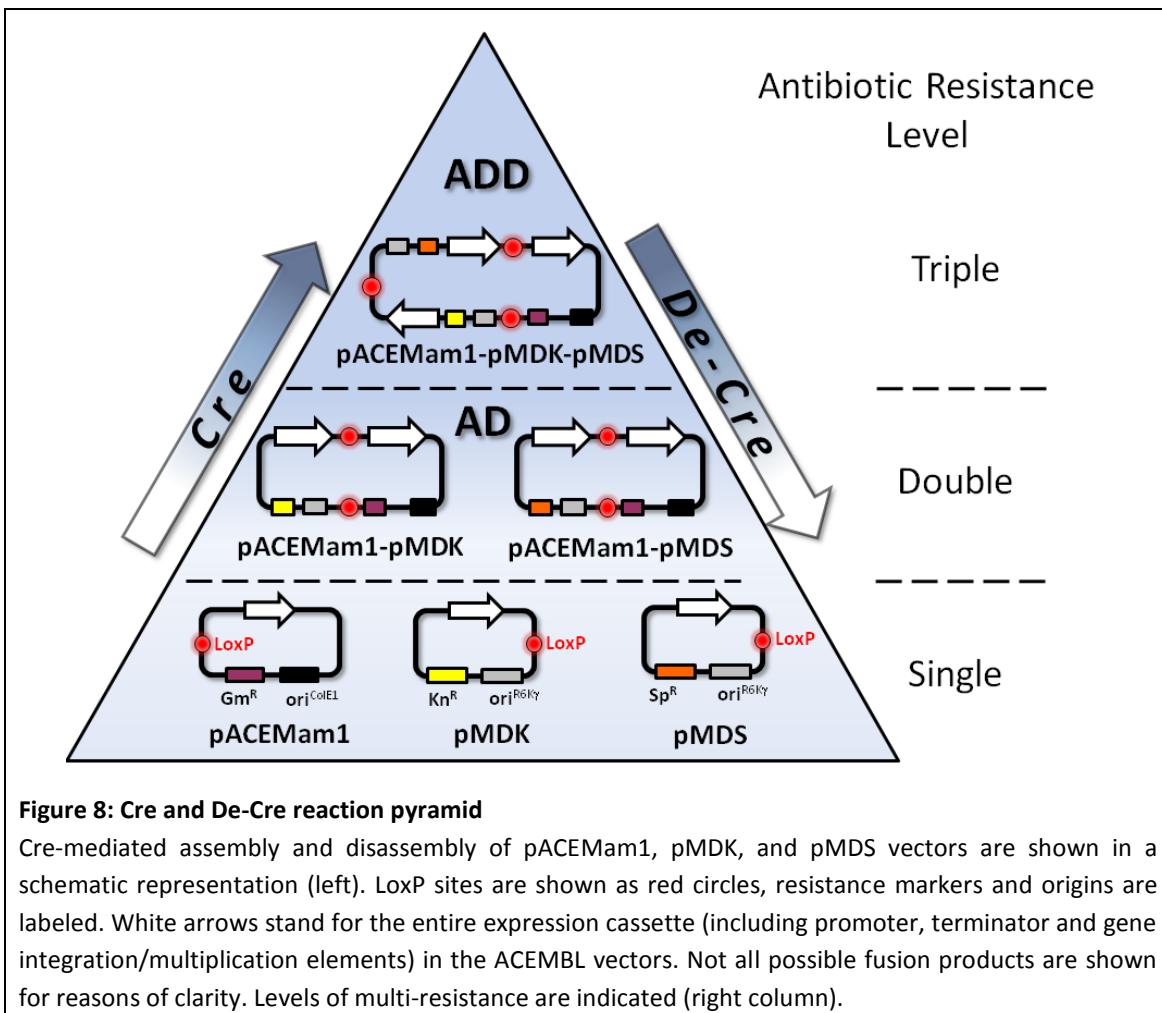

The site-specific recombination mediated by Cre recombinase involves the formation of a Holliday junction (HJ). The recombination events catalyzed by Cre recombinase depend on the location and relative orientation of the loxP sites. Two DNA molecules, for example an acceptor and a donor plasmid, containing single loxP sites will be fused. Furthermore, the Cre recombination is an equilibrium reaction with 20-30% efficiency in recombination. This provides useful options for multi-gene combinations for multi-protein complex expression.

**Figure 7: LoxP imperfect inverted repeat**

In a reaction where several DNA molecules such as donors and acceptors are incubated with Cre recombinase, the fusion/excision activity of the enzyme will result in an equilibrium state where single vectors (educt vectors) and all possible fusions coexist. Donor vectors can be used with acceptors and/or donors, and vice versa. Higher order fusions are also generated where more than two vectors are fused. This is shown schematically in Illustration 6.

The fact that Donors contain a conditional origin of replication that depends on a *pir*<sup>+</sup> (*pir* positive) background now allows for selecting out from this reaction mix all desired Acceptor-Donor(s) combinations. For this, the reaction mix is used to transform *pir* negative strains (TOP10, DH5 $\alpha$ , HB101 or other common laboratory cloning strains). Then, Donor vectors will act as suicide vectors when plated out on agar containing the antibiotic corresponding to the Donor encoded resistance marker, unless fused with an Acceptor. By using agar with the appropriate combinations of antibiotics, all desired Acceptor-Donor fusions can be selected for.

### C.2.3. Combining HE/BstXI cycling and Cre-Lox recombination

Of course, both methods can also be combined to generate multiple gene-expression cassette constructs. To this end, you can introduce multiple gene cassettes with the homing endonuclease/BstXI protocol into different Acceptor/Donor vectors and then fuse these using the Cre-Lox modules (illustrated in figure 2a).

## D. Protocols

### D.0 Introductory remarks

Please note that the bacteria in the agar stabs have not been made competent for transformation. If you wish to use them to transform your constructs, you will have to prepare competent cells. This applies specifically to the pirHC and pirLC strains used to maintain donor constructs. You may follow your preferred protocol for preparing chemically or electrocompetent cells, e.g. Inoue et al. (1990) or variations of this protocol, or standard protocols as described in Current Protocols in Molecular Biology or Sambrook and Russell: Molecular Cloning (3<sup>rd</sup> edition, 2001, or older versions).

### D.1 Cloning into pACEMam or pMDx transfer vectors

#### Reagents:

Restriction endonucleases

DNA ligase

*E. coli* competent cells

Antibiotics: Chloramphenicol, Gentamycin, Kanamycin, Spectinomycin

The genes of choice are cloned using standard cloning procedures into the multiple cloning sites MCS (see *Supplementary Information*) of pACEMam1/2 and pMDC, pMDK, pMDS. Ligation reactions for pACEMam derivatives are transformed into standard *E. coli* cells for cloning (such as TOP10, DH5 $\alpha$ , HB101) and plated on agar containing gentamycin (7  $\mu$ g/ml). Ligation reactions for pIDx derivatives are transformed into *E. coli* cells expressing the *pir* gene (pirHC and pirLC from this kit – in this case you will need to make the cells electro- or chemically competent first; other strains, e.g. BW23473, BW23474) and plated on agar containing chloramphenicol (pMDC; 25  $\mu$ g/ml), kanamycin (pMDK; 50  $\mu$ g/ml) or spectinomycin (pMDS; 50  $\mu$ g/ml). Correct clones are selected based on specific restriction digestion patterns and DNA sequencing of the inserts.

### D.2 Multiplication by using the HE and BstXI sites

ACEMBL *MultiMam* donor vectors contain a recognition site for the homing endonuclease PI-Scel (fig. 3). Upon cleavage, this HE site yields a 3' overhang with the sequence -GTGC. Acceptor vectors contain the homing endonuclease site I-CeuI (see fig. 2), which upon cleavage will result in a 3' overhang of -CTAA. On acceptors and donors, the respective HE site precedes the MCS (see fig. 2 and 3). The 3' end

of the MIE contains a specifically designed BstXI site, which upon cleavage will generate a matching overhang. The basis of this is the specificity of cleavage by BstXI. The recognition sequence of BstXI is defined as CCANNNNN'NTGG (the apostrophe marks the position of the phosphodiester link cleavage). The residues denoted as N can be chosen freely. Donor vectors thus contain a BstXI recognition site with the sequence CCATGTGC'CTGG, and Acceptor vectors contain CCATCTAA'TTGG. The overhangs generated by BstXI cleavage in each case will match the overhangs generated by HE cleavage. Note that Acceptors and Donors have different HE sites.

The recognition sites are not symmetric. Therefore, ligation of a HE/BstXI digested fragment into a HE site of an ACEMBL MultiMam vector will be (1) directional and (2) result in a hybrid DNA sequence where a HE halfsite is combined with a BstXI half site (see figure 5). This site will be cut by neither the HE nor BstXI. Therefore, in a construct that has been digested with a HE, insertion by ligation of HE/BstXI digested DNA fragment containing an expression cassette with one or several genes will result in a construct which contains all heterologous genes of interest, enveloped by an intact HE site in front, and a BstXI site at the end. Therefore, the process of integrating entire expression cassettes by means of HE/BstXI digestion and ligation into a HE site can be repeated iteratively.

## Protocol 1. Multiplication by using homing endonuclease/BstXI.

### Reagents required:

Homing endonucleases PI-SceI, I-CeuI  
10x Buffers for homing endonucleases  
Restriction enzyme BstXI (and 10x Buffer)  
T4 DNA ligase (and 10x Buffer)  
*E. coli* competent cells  
Antibiotics

### Step 1: Insert preparation

Restriction reactions are carried out in 40 µl reaction volumes, using homing endonucleases PI-SceI (Donors) or I-CeuI (Acceptors) as recommended by the supplier.

|  |       |
|--|-------|
| Acceptor or donor plasmid ( $\geq 0.5 \mu\text{g}$ ) in ddH <sub>2</sub> O | 32 µl |
| 10x restriction enzyme buffer  | 4 µl  |
| 10 mM BSA  | 2 µl  |
| PI-SceI (Donors) or I-CeuI (acceptors)                                     | 2 µl  |

Reactions are then purified using a PCR extraction kit or by acidic ethanol precipitation, and subsequently digested with BstXI according to the supplier's recommendations.

|                                       |       |
|---------------------------------------|-------|
| HE digested DNA in ddH <sub>2</sub> O | 32 µl |
| 10x restriction enzyme buffer         | 4 µl  |
| 10 mM BSA                             | 2 µl  |
| BstXI                                 | 2 µl  |

Gel extraction of insert(s):

Processed insert is then purified by agarose gel extraction using commercial kits (Qiagen, Macherey Nagel etc). Elution of the extracted DNA in the minimal volume defined by the manufacturer is recommended.

**Step 2:** Vector preparation

Restriction reactions are carried out in 40 µl reaction volumes, using homing endonucleases PI-Scel (Donors) or I-CeuI (Acceptors) as recommended by the supplier.

|  |       |
|--|-------|
| Acceptor or donor plasmid ( $\geq 0.5 \mu\text{g}$ ) in ddH <sub>2</sub> O | 33 µl |
| 10x Restriction enzyme buffer  | 4 µl  |
| 10 mM BSA  | 2 µl  |
| PI-Scel (Donors) or I-CeuI (acceptors)                                     | 1 µl  |

Reactions are then purified by PCR extraction kit or acidic ethanol precipitation, and next treated with intestinal alkaline phosphatase according to the supplier's recommendations. Dephosphorylation is performed to minimize vector re-annealing and to increase integration of the insert.

|                                       |       |
|---------------------------------------|-------|
| HE digested DNA in ddH <sub>2</sub> O | 17 µl |
| 10x Alkaline phosphatase buffer       | 2 µl  |
| Alkaline phosphatase                  | 1 µl  |

Gel extraction of vector:

Processed vector is then purified by agarose gel extraction using commercial kits (Qiagen, MachereyNagel etc). Elution of the extracted DNA in the minimal volume defined by the manufacturer is recommended.

**Step 3:** Ligation

Ligation reactions are carried out in 20 µl reaction volumes:

|   |        |
|---|--------|
| HE/Phosphatase treated vector (gel extracted) | 4 µl   |
| HE/BstXI treated insert (gel extracted)       | 14 µl  |
| 10x T4 DNA Ligase buffer                      | 2 µl   |
| T4 DNA Ligase                                 | 0.5 µl |

Ligation reactions are performed at 25°C for 1h or at 16°C overnight.

**Step 4:** Transformation

Mixtures are next transformed into competent cells following standard transformation procedures.

Ligation reactions for pACEMam1 and pACEMam2 derivatives are transformed into standard *E. coli* cells for cloning (such as TOP10, DH5 $\alpha$ , HB101) and, after recovery, are plated on agar containing gentamycin (7  $\mu$ g/ml).

Reactions for Donor derivatives are transformed into *E. coli* cells expressing the *pir* gene (such as BW23473, BW23474, or PIR1 and PIR2 from Invitrogen and, of course, pirLC and pirHC in this kit) and plated on agar containing chloramphenicol (25  $\mu$ g/ml, pMDC), kanamycin (50  $\mu$ g/ml, pMDK), or spectinomycin (50  $\mu$ g/ml, pMDS).

#### **Step 5: Plasmid analysis**

Plasmids are cultured and correct clones selected based on specific restriction digestion and DNA sequencing of the inserts.

### **D.3 Cre-LoxP reaction of Acceptors and Donors**

#### **D 3.1. Protocol 2: Cre-LoxP fusion of Acceptors and Donors**

This protocol is designed for generating multigene fusions from Donors and Acceptors by Cre-LoxP reaction.

##### Reagents:

Cre recombinase (from NEB or self-made)

Standard *E. coli* competent cells (*pir*<sup>-</sup> strain)

Antibiotics

96-well microtiter plates

12 well tissue-culture plates (or Petri dishes) w. agar/antibiotics

LB medium

1. For a 20  $\mu$ l Cre reaction, mix 1-2  $\mu$ g of each educt in approximately equal amounts. Add ddH<sub>2</sub>O to adjust the total volume to 16-17  $\mu$ l, then add 2  $\mu$ l 10x Cre buffer and 1-2  $\mu$ l Cre recombinase (1-2 U).

2. Incubate Cre reaction at 37°C (or 30°C) for 1 hour.

3. Optional: load 2-5  $\mu$ l of Cre reaction on an analytical agarose gel for examination.

*Heat inactivation at 70°C for 10 minutes before gel loading is strongly recommended.*

4. For chemical transformation, mix 10-15  $\mu$ l Cre reaction with 200  $\mu$ l chemically competent cells. Incubate the mixture on ice for 15-30 minutes. Then perform heat shock at 42°C for 45-60 s.

*Up to 20  $\mu$ l Cre reaction (0.1 volumes of the chemically competent cell suspension) can be directly transformed into 200  $\mu$ l chemical competent cells.*

For electrotransformation, up to 2 µl Cre reaction can be directly mixed with 100 µl electrocompetent cells, and transformed by using an electroporator (e.g. BIORAD *E. coli* Pulser) at 1.8-2.0 kV.

*Larger volumes of Cre reaction must be desalted by ethanol precipitation or via PCR purification columns before electrotransformation. The desalted Cre reaction mix should not exceed 0.1 volumes of the electrocompetent cell suspension.*

*The cell/DNA mixture can be immediately used for electrotransformation without prolonged incubation on ice.*

5. Add up to 400 µl of LB (or SOC) medium per 100 µl of cell/DNA suspension immediately after the transformation (heat shock or electroporation).
6. Incubate the suspension in a 37°C shaking incubator overnight or for at least 4 hours (recovery period).

*To recover multifusion plasmid containing more than 2 resistance markers, it is strongly recommended to incubate the suspension at 37°C overnight.*

7. Plate out the recovered cell suspension on agar containing the desired combination of antibiotics. Incubate at 37°C overnight.
8. Clones from colonies present after overnight incubation can be verified by restriction digestion at this stage (refer to steps 12-16).

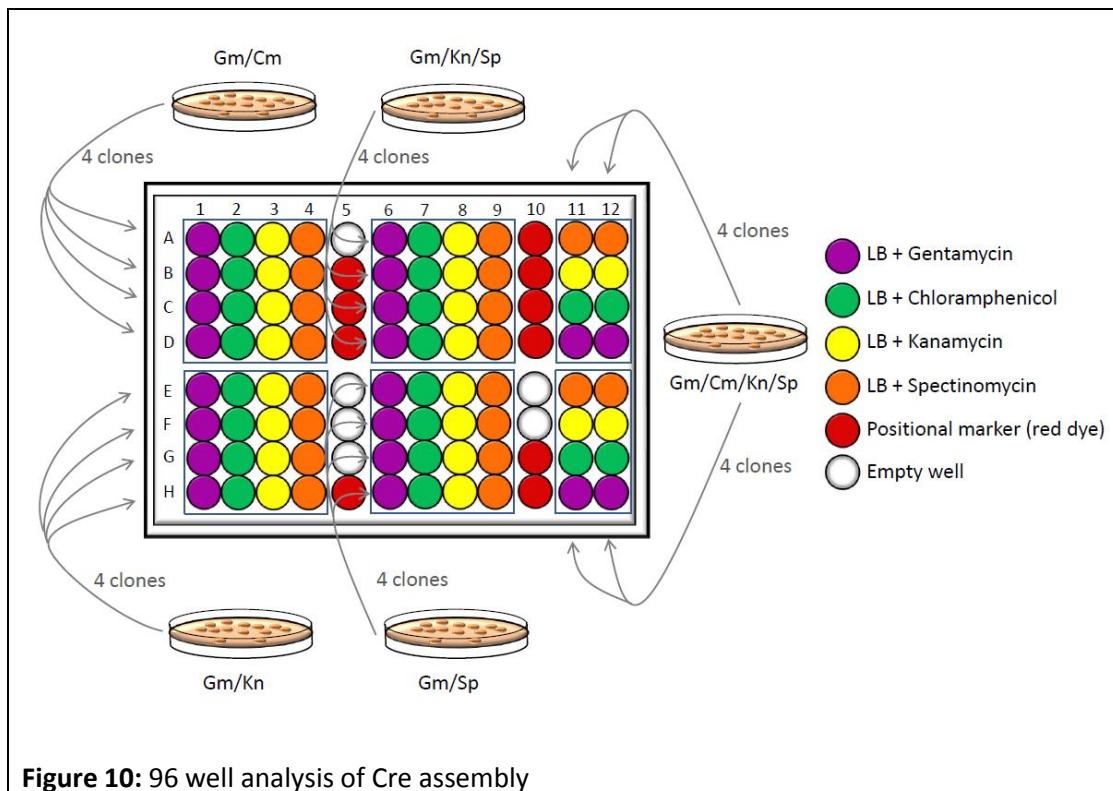

*This quality control step should be carried out especially in the case that only one specific multifusion plasmid is desired.*

For further selection by single antibiotic challenges on a 96 well microtiter plate, continue to step 9.

*Several to many different multifusion plasmid combinations can be processed and selected in parallel on one 96 well microtiter plate.*

9. For 96 well antibiotic tests, inoculate four colonies from each agar plate with different antibiotic combinations into approx. 500 µl LB medium without antibiotics. Incubate the cell cultures in a 37°C shaking incubator for 1-2 hours.
10. While incubating the colonies, fill a 96-well microtiter plate with 150 µl antibiotic-containing LB medium (following Illustration 7). It is recommended to add coloured dye (positional marker) in the wells indicated.

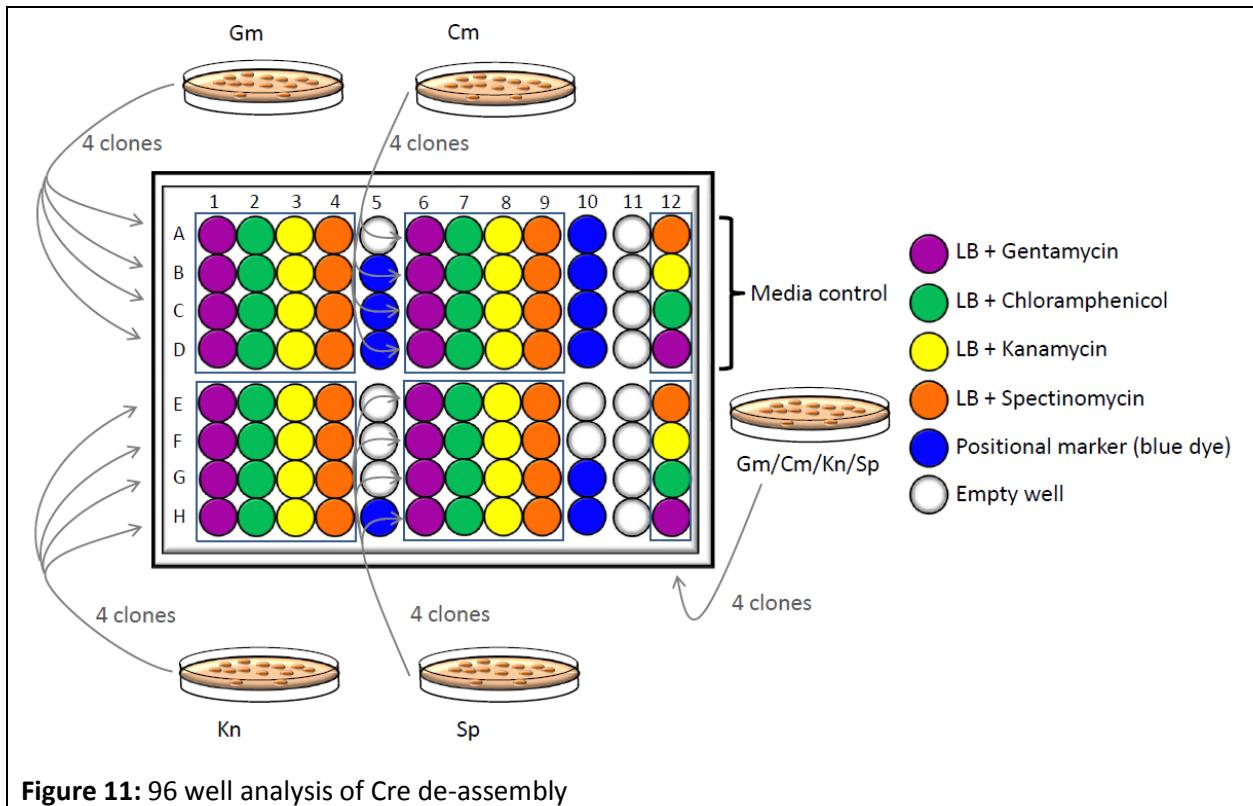

*A typical arrangement of the solutions, which is used for parallel selections of multifusion plasmids, is shown in Illustration 10. The concept behind the 96 well plate experiment is that every cell suspension from single colonies needs to be challenged by all four single antibiotics for unambiguous interpretation.*

11. Add 1  $\mu$ l aliquots of pre-incubated cell culture (Step 9) to the corresponding wells. Then incubate the inoculated 96 well microtiter plate in a 37°C shaking incubator overnight at 180-200 rpm.
- Recommended: use parafilm or any other adhesive seal to wrap the plate to avoid drying out.  
The remainder of the pre-incubated cell cultures can be kept at 4°C for further inoculations if necessary.*
12. Select transformants containing desired multifusion plasmids based on antibiotic resistance, according to the combination of dense (positive) and clear (no growth) cell microcultures from each colony. Inoculate 10-20  $\mu$ l cell culture into 10 ml LB media with corresponding antibiotics. Incubate in a 37°C shaking incubator overnight.
  13. Centrifuge the overnight cell cultures at 4000g for 5-10 minutes. Purify plasmid from the resulting cell pellets with common plasmid miniprep kits, according to manufacturer's recommendation.
  14. Determine the concentrations of purified plasmid solutions by using UV absorption spectrophotometry (e.g. by using a NanoDrop™ 1000 machine).
  15. Digest 0.5-1  $\mu$ g of the purified plasmid solution in a 20  $\mu$ l restriction digestion with appropriate endonuclease(s). Incubate under recommended reaction condition for approx. 2 hours.
  16. Use 5-10  $\mu$ l of the digestion for analytical agarose (0.8-1.2%) gel electrophoresis. Verify plasmid integrity by comparing the experimental restriction pattern to a restriction pattern predicted *in silico* (e.g. by using program VectorNTI from Invitrogen or similar programs).

### D 3.2. Protocol 3. Deconstruction of fusion vectors by Cre

The following protocol is suitable for releasing any single educt from multifusion constructs (deconstruction). This is achieved by Cre-LoxP reaction, transformation and plating on agar with appropriately reduced antibiotic resistance level (cf. figure 9). In the liberated educt entity, encoding genes can be modified and diversified. Then, the diversified construct is resupplied by Cre-LoxP reaction (C3.1).

#### Reagents:

Cre recombinase (and 10x Buffer)

*E. coli* competent cells

(*pir*<sup>+</sup> strains, *pir*<sup>-</sup> strains can be used only when partially deconstructed Acceptor-Donor fusions are desired).

#### Antibiotics

1. Incubate approx. 1 µg multifusion plasmid with 2 µl 10x Cre buffer, 1-2 µl Cre recombinase, add ddH<sub>2</sub>O to adjust the total reaction volume to 20 µl.
2. Incubate this Cre deconstruction reaction mixture at 30°C for 1 to 4 hour(s).
3. Optional: load 2-5 µl of the reaction on an analytical agarose gel for examination.

*Heat inactivation at 70°C for 10 minutes before gel loading is strongly recommended.*

4. For chemical transformation, mix 10-15 $\mu$ l De-Cre reaction with 200  $\mu$ l chemically competent cells. Incubate the mixture on ice for 15-30 minutes. Then perform heat shock at 42°C for 45-60 s.

*Up to 20  $\mu$ l De-Cre reaction (0.1 volumes of the chemical competent cell suspension) can be directly transformed into 200  $\mu$ l chemically competent cells.*

For electrotransformation, up to 2  $\mu$ l De-Cre reaction can be directly mixed with 100  $\mu$ l electrocompetent cells, and transformed by using an electroporator (e.g. BIORAD *E. coli* Pulser) at 1.8-2.0 kV.

*Larger volume of De-Cre reaction must be desalted by ethanol precipitation or PCR purification column prior to electrotransformation. The desalted De-Cre reaction mix should not exceed 0.1 volumes of the electrocompetent cell suspension.*

*The cell/DNA mixture can be immediately used for electrotransformation without prior incubation on ice.*

5. Add up to 400  $\mu$ l of LB media (or SOC media) per 100  $\mu$ l of cell/DNA suspension immediately after the transformation (heat shock or electroporation).

6. Incubate the suspension in a 37°C shaking incubator (recovery).

*For recovery of partially deconstructed double/triple fusions, incubate the suspension in a 37°C shaking incubator for 1 to 2 hours.*

*For recovery of individual educts, incubate the suspension in a 37°C shaking incubator overnight or for at least 4 hours.*

7. Plate out the recovered cell suspension on agar containing the desired (combination of) antibiotic(s). Incubate at 37°C overnight.

8. Colonies after overnight incubation can be verified directly by restriction digestion at this stage (refer to steps 12-16).

*This is especially recommended in cases where only a single educt or partially deconstructed multifusion plasmid is desired.*

For further selection by single antibiotic challenge on a 96 well microtiter plate, continue with step 9.

*Several different single educts/partially deconstructed multifusion plasmids can be processed and selected in parallel on one 96 well microtiter plate.*

9. For 96 well analysis, inoculate four colonies each from agar plates containing a defined set of antibiotics into approx. 500  $\mu$ l LB medium without antibiotics. Incubate the cell cultures in a 37°C shaking incubator for 1-2 hours.

10. While incubating the colonies, fill a 96 well microtiter plate with 150  $\mu$ l antibiotic-containing LB medium or dye (positional marker) in the corresponding wells.

*Refer to figures 10 and 11 for the arrangement of the solutions in the wells, which are used for parallel selection of single educts or partially deconstructed multifusion plasmids. The concept is that every cell suspension from a single colony needs to be challenged by all four antibiotics separately for unambiguous interpretation.*

11. Add 1  $\mu$ l aliquots from the pre-incubated cell cultures (Step 9) into the corresponding wells. Incubate the 96 well microtiter plate in a 37°C shaking incubator overnight at 180-200 rpm.

*Recommended: use parafilm to wrap the plate to prevent desiccation.*

*The remainder of the pre-incubated cell cultures can be kept at 4°C in a refrigerator for further inoculations if necessary.*

12. Select transformants containing desired single educts or partially deconstructed multifusion plasmids according to the combination of dense (growth) and clear (no growth) cell cultures from each colony. Inoculate 10-20 µl from the cell cultures into 10 ml LB media with corresponding antibiotic(s). Incubate in a 37°C shaking incubator overnight.
13. The next day, centrifuge the overnight cell cultures at 4000g for 5-10 minutes. Purify plasmid from cell pellets with common plasmid miniprep kits, according to manufacturers' protocols.
14. Determine the concentrations of purified plasmid solutions by using UV absorption spectroscopy (e.g. NanoDrop<sup>TM</sup> 1000).
15. Digest 0.5-1 µg of the purified plasmid solution in a 20 µl restriction digestion (with 5-10 units endonuclease). Incubate under recommended reaction condition for approx. 2 hours.
16. Use 5-10 µl of the digestion for analytical agarose gel (0.8-1.2%) electrophoresis. Verify plasmid integrity by comparing the *de facto* restriction pattern to the *in silico* predicted restriction pattern (e.g. by using VectorNTI, Invitrogen, or any other similar program).
17. Optional: Occasionally, a deconstruction reaction is not complete but yields partially deconstructed fusions which still retain entities to be eliminated. In this case, we recommend to pick these partially deconstructed fusions containing and perform a second round of Cre deconstruction reaction (repeat steps 1-8) by using this construct as starting material.

## E. Appendix

### E.1. Preparing bacterial stock from agar stabs

We recommend that you prepare your personal bacterial stock from the agar stabs you received in the kit or transform your laboratory strain of choice with the vectors (please note that for the donor vectors this needs to be a pir+ strain). This is advisable since agar stabs only have a limited shelf life.

To generate your bacterial stock for long-term storage, streak bacteria from the agar stab onto an appropriate selective plate (refer to the vector maps for acceptor and donor vectors) or plates without antibiotics (pirHC and pirLC strains; we recommend to test these strains against a panel of antibiotics to be on the safe side; no growth of colonies should be observed under conditions of antibiotic selection). Incubate the plates over night at 37°C and then proceed to prepare stocks from individual colonies for long-term storage according to your protocol of choice (glycerol, DMSO, etc.), as described, for example, in Inoue et al. (1990), Molecular Cloning (Sambrook and Russell, 2000), Current Protocols in Molecular Biology (Ausubel et al., 1994), etc.

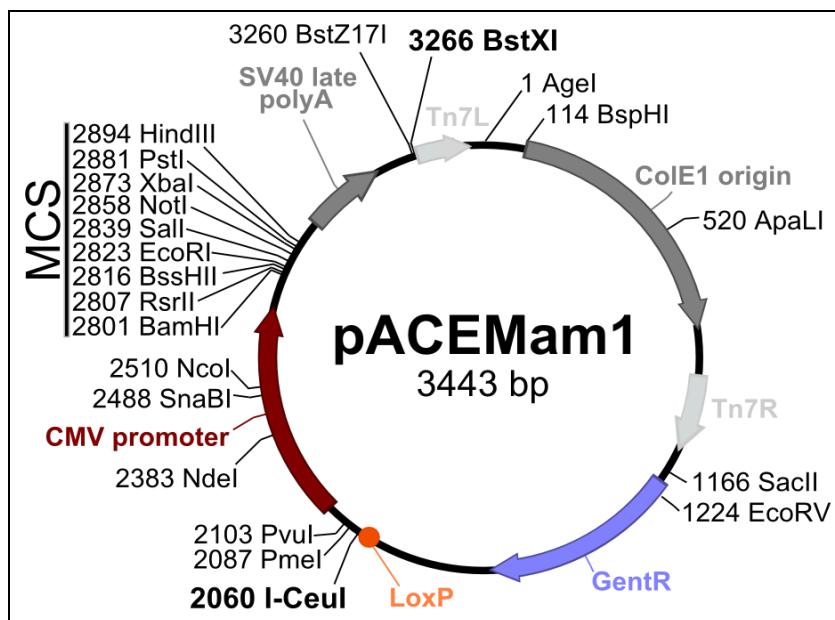

## E.2. ACEMBL *MultiMam* vectors: maps, sequences, MCS, restriction

Note: All vector sequences can be provided in electronic format, as files compatible with the ApE (A plasmid Editor, v2.0.36 or 2.0.37) sequence analysis and presentation software, on request. These sequences contain all relevant information that is also summarized in the circle maps.

Acceptor and donor vectors are presented as circle maps and, in addition, the multiple cloning site (MCS) of each vector is shown featuring relevant unique restriction sites. Moreover, you will find, for the purposes of designing a restriction strategy, a non-exhaustive list of restriction endonucleases that cut once, twice or not at all. Additional restriction sites can be identified with any sequence analysis software, e.g. VectorNTI, ApE, etc. or by using online tools such as WebCutter 2.0 (<http://rna.lundberg.gu.se/cutter2>) or the NEB cutter V2.0 (<http://tools.neb.com/NEBcutter2/>).
